# ROM-RSA

# The RSA Assumption

**Definition.** The RSA assumption states that if:

1.  $N = pq$  factors into two randomly chosen primes  $p$  and  $q$  of the same bit-size,
2.  $e$  is in  $\mathbb{Z}_{\phi(N)}^*$ ,
3.  $m$  is randomly chosen in  $\mathbb{Z}_N^*$ ,

then for every polynomial time algorithm  $A$

$$\Pr[A(N, e, m^e \bmod N) = m]$$

is negligible.

## Semantically Secure ROM-RSA (1/2)

Suppose that  $f : \{0, 1\}^n \rightarrow \{0, 1\}^n$  is a randomly chosen function (a random oracle).

- ▶ **Key Generation.** Choose a random RSA key pair  $((N, e), (p, q, d))$ , with  $\log_2 N = n$ .
- ▶ **Encryption.** Encrypt a plaintext  $m \in \{0, 1\}^n$  by choosing  $r \in \mathbb{Z}_N^*$  randomly and computing

$$(u, v) = (r^e \bmod N, f(r) \oplus m) .$$

- ▶ **Decryption.** Decrypt a ciphertext  $(u, v)$  by

$$m = v \oplus f(u^d \bmod N) .$$

## Semantically Secure RSA in the ROM (2/2)

- ▶ We increase the ciphertext size by a factor of two.
- ▶ Our analysis is in the random oracle model, **which is unsound!**

## Semantically Secure RSA in the ROM (2/2)

- ▶ We increase the ciphertext size by a factor of two.
- ▶ Our analysis is in the random oracle model, **which is unsound!**

### Solutions.

- ▶ Using a “optimal” padding the first problem can be reduced. See standard OAEP+.

## Semantically Secure RSA in the ROM (2/2)

- ▶ We increase the ciphertext size by a factor of two.
- ▶ Our analysis is in the random oracle model, **which is unsound!**

### Solutions.

- ▶ Using a “optimal” padding the first problem can be reduced. See standard OAEP+.
- ▶ Using a scheme with much lower rate, the second problem can be removed.

# Rabin

## Key Generation.

- ▶ Choose  $n$ -bit primes  $p$  and  $q$  such that  $p, q \equiv 3 \pmod{4}$  randomly and define  $N = pq$ .
- ▶ Output the key pair  $(N, (p, q))$ , where  $N$  is the public key and  $(p, q)$  is the secret key.

## Rabin's Cryptosystem (2/3)

**Encryption.** Encrypt a plaintext  $m$  by computing

$$c = m^2 \bmod N .$$

**Decryption.** Decrypt a ciphertext  $c$  by computing

$$m = \sqrt{c} \bmod N .$$

## Rabin's Cryptosystem (2/3)

**Encryption.** Encrypt a plaintext  $m$  by computing

$$c = m^2 \bmod N .$$

**Decryption.** Decrypt a ciphertext  $c$  by computing

$$m = \sqrt{c} \bmod N .$$

There are **four** roots, so which one should be used?

## Rabin's Cryptosystem (3/3)

Suppose  $y$  is a quadratic residue modulo  $p$ .

$$\begin{aligned} \left(\pm y^{(p+1)/4}\right)^2 &= y^{(p+1)/2} \pmod{p} \\ &= y^{(p-1)/2} y \pmod{p} \\ &= \left(\frac{y}{p}\right) y \\ &= y \pmod{p} \end{aligned}$$

In Rabin's cryptosystem:

- ▶ Find roots for  $y_p = y \pmod{p}$  and  $y_q = y \pmod{q}$ .
- ▶ Combine roots to get the four roots modulo  $N$ . Choose the "right" root and output the plaintext.

# Security of Rabin's Cryptosystem

**Theorem.** Breaking Rabin's cryptosystem is equivalent to factoring.

**Idea.**

1. Choose random element  $r$ .
2. Hand  $r^2 \bmod N$  to adversary.
3. Consider outputs  $r'$  from the adversary such that  $(r')^2 = r^2 \bmod N$ . Then  $r' \neq \pm r \bmod N$ , with probability  $1/2$ , in which case  $\gcd(r' - r, N)$  gives a factor of  $N$ .

## A Goldwasser-Micali Variant of Rabin

**Theorem [CG98].** If factoring is hard and  $r$  is a random quadratic residue modulo  $N$ , then for every polynomial time algorithm  $A$

$$\Pr[A(N, r^2 \bmod N) = \text{lsb}(r)]$$

is negligible.

- ▶ **Encryption.** Encrypt a plaintext  $m \in \{0, 1\}$  by choosing a random quadratic residue  $r$  modulo  $N$  and computing

$$(u, v) = (r^2 \bmod N, \text{lsb}(r) \oplus m) .$$

- ▶ **Decryption.** Decrypt a ciphertext  $(u, v)$  by

$$m = v \oplus \text{lsb}(\sqrt{u}) \quad \text{where } \sqrt{u} \text{ is a quadratic residue .}$$

# Diffie-Hellman

# Diffie-Hellman Key Exchange (1/3)

Diffie and Hellman asked themselves:

How can two parties efficiently agree on a secret key using only **public** communication?

# Diffie-Hellman Key Exchange (2/3)

## Construction.

Let  $G$  be a cyclic group of order  $q$  with generator  $g$ .

- ▶ Alice picks  $a \in \mathbb{Z}_q$  randomly, computes  $y_a = g^a$  and hands  $y_a$  to Bob.
  - ▶ Bob picks  $b \in \mathbb{Z}_q$  randomly, computes  $y_b = g^b$  and hands  $y_b$  to Alice.
- ▶ Alice computes  $k = y_b^a$ .
  - ▶ Bob computes  $k = y_a^b$ .
3. The joint secret key is  $k$ .

## Problems.

- ▶ Susceptible to man-in-the-middle attack without authentication.
- ▶ How do we map a random element  $k \in G$  to a random symmetric key in  $\{0, 1\}^n$ ?

# The El Gamal Cryptosystem (1/2)

**Definition.** Let  $G$  be a cyclic group of order  $q$  with generator  $g$ .

- ▶ The **key generation** algorithm chooses a random element  $x \in \mathbb{Z}_q$  as the private key and defines the public key as

$$y = g^x .$$

- ▶ The **encryption** algorithm takes a message  $m \in G$  and the public key  $y$ , chooses  $r \in \mathbb{Z}_q$ , and outputs the pair

$$(u, v) = E_y(m, r) = (g^r, y^r m) .$$

- ▶ The **decryption** algorithm takes a ciphertext  $(u, v)$  and the secret key and outputs

$$m = D_x(u, v) = vu^{-x} .$$

## The El Gamal Cryptosystem (2/2)

- ▶ El Gamal is essentially Diffie-Hellman + OTP.
- ▶ Homomorphic property (with public key  $y$ )

$$E_y(m_0, r_0)E_y(m_1, r_1) = E_y(m_0m_1, r_0 + r_1) .$$

This property is very important in the construction of cryptographic protocols!

# Discrete Logarithm (1/2)

**Definition.** Let  $G$  be a cyclic group of order  $q$  and let  $g$  be a generator  $G$ . The **discrete logarithm** of  $y \in G$  in the basis  $g$  (written  $\log_g y$ ) is defined as the unique  $x \in \{0, 1, \dots, q - 1\}$  such that

$$y = g^x .$$

Compare with a “normal” logarithm! ( $\ln y = x$  iff  $y = e^x$ )

## Discrete Logarithm (2/2)

**Example.** 7 is a generator of  $\mathbb{Z}_{12}$  additively, since  $\gcd(7, 12) = 1$ .

What is  $\log_7 3$ ?

## Discrete Logarithm (2/2)

**Example.** 7 is a generator of  $\mathbb{Z}_{12}$  additively, since  $\gcd(7, 12) = 1$ .

What is  $\log_7 3$ ? ( $9 \cdot 7 = 63 = 3 \pmod{12}$ , so  $\log_7 3 = 9$ )

## Discrete Logarithm (2/2)

**Example.** 7 is a generator of  $\mathbb{Z}_{12}$  additively, since  $\gcd(7, 12) = 1$ .

What is  $\log_7 3$ ? ( $9 \cdot 7 = 63 = 3 \pmod{12}$ , so  $\log_7 3 = 9$ )

**Example.** 7 is a generator of  $\mathbb{Z}_{13}^*$ .

What is  $\log_7 9$ ?

## Discrete Logarithm (2/2)

**Example.** 7 is a generator of  $\mathbb{Z}_{12}$  additively, since  $\gcd(7, 12) = 1$ .

What is  $\log_7 3$ ? ( $9 \cdot 7 = 63 = 3 \pmod{12}$ , so  $\log_7 3 = 9$ )

**Example.** 7 is a generator of  $\mathbb{Z}_{13}^*$ .

What is  $\log_7 9$ ? ( $7^4 = 9 \pmod{13}$ , so  $\log_7 9 = 4$ )

# Discrete Logarithm Assumption

Let  $G_{q_n}$  be a cyclic group of prime order  $q_n$  such that  $\lfloor \log_2 q_n \rfloor = n$  for  $n = 2, 3, 4, \dots$ , and denote the family  $\{G_{q_n}\}_{n \in \mathbb{N}}$  by  $G$ .

**Definition.** The **Discrete Logarithm (DL) Assumption** in  $G$  states that if generators  $g_n$  and  $y_n$  of  $G_{q_n}$  are randomly chosen, then for every polynomial time algorithm  $A$

$$\Pr [A(g_n, y_n) = \log_{g_n} y_n]$$

is negligible.

# Discrete Logarithm Assumption

Let  $G_{q_n}$  be a cyclic group of prime order  $q_n$  such that  $\lfloor \log_2 q_n \rfloor = n$  for  $n = 2, 3, 4, \dots$ , and denote the family  $\{G_{q_n}\}_{n \in \mathbb{N}}$  by  $G$ .

**Definition.** The **Discrete Logarithm (DL) Assumption** in  $G$  states that if generators  $g$  and  $y$  of  $G$  are randomly chosen, then for every polynomial time algorithm  $A$

$$\Pr [A(g, y) = \log_g y]$$

is negligible.

We usually remove the indices from our notation!

**Definition.** Let  $g$  be a generator of  $G$ . The **Diffie-Hellman (DH) Assumption** in  $G$  states that if  $a, b \in \mathbb{Z}_q$  are randomly chosen, then for every polynomial time algorithm  $A$

$$\Pr \left[ A(g^a, g^b) = g^{ab} \right]$$

is negligible.

# Decision Diffie-Hellman Assumption

**Definition.** Let  $g$  be a generator of  $G$ . The **Decision Diffie-Hellman (DDH) Assumption** in  $G$  states that if  $a, b, c \in \mathbb{Z}_q$  are randomly chosen, then for every polynomial time algorithm  $A$

$$\left| \Pr \left[ A(g^a, g^b, g^{ab}) = 1 \right] - \Pr \left[ A(g^a, g^b, g^c) = 1 \right] \right|$$

is negligible.

## Relating DL Assumptions

- ▶ Computing discrete logarithms is at least as hard as computing a Diffie-Hellman element  $g^{ab}$  from  $g^a$  and  $g^b$ .
- ▶ Computing a Diffie-Hellman element  $g^{ab}$  from  $g^a$  and  $g^b$  is at least as hard as distinguishing a Diffie-Hellman triple  $(g^a, g^b, g^{ab})$  from a random triple  $(g^a, g^b, g^c)$ .
- ▶ In most groups where the DL assumption is conjectured, DH and DDH assumptions are conjectured as well.
- ▶ There exists special elliptic curves where DDH problem is easy, but DH assumption is conjectured!

- ▶ Finding the secret key is equivalent to DL problem.
- ▶ Finding the plaintext from the ciphertext and the public key and is equivalent to DH problem.
- ▶ The semantic security of El Gamal is equivalent to DDH problem.

# Brute Force and Shank's

Let  $G$  be a cyclic group of order  $q$  and  $g$  a generator. We wish to compute  $\log_g y$ .

- ▶ **Brute Force.**  $O(q)$
- ▶ **Shanks.** Time and **Space**  $O(\sqrt{q})$ .
  1. Set  $z = g^m$  (think of  $m$  as  $m = \sqrt{q}$ ).
  2. Compute  $z^i$  for  $0 \leq i \leq q/m$ .
  3. Find  $0 \leq j \leq m$  and  $0 \leq i \leq q/m$  such that  $yg^j = z^i$  and output  $x = mi - j$ .

# Birthday Paradox

**Lemma.** Let  $q_0, \dots, q_k$  be randomly chosen in a set  $S$ . Then

1. the probability that  $q_i = q_j$  for some  $i \neq j$  is approximately  $1 - e^{-\frac{k^2}{2s}}$ , where  $s = |S|$ , and
2. with  $k \approx \sqrt{-2s \ln(1 - \delta)}$  we have a collision-probability of  $\delta$ .

**Proof.**

$$\left(\frac{s-1}{s}\right) \left(\frac{s-2}{s}\right) \cdot \dots \cdot \left(\frac{s-k}{s}\right) \approx \prod_{i=1}^k e^{-\frac{i}{s}} \approx e^{-\frac{k^2}{2s}} .$$
